

# Counting flags in triangle-free digraphs

Jan Hladky (joint with with Daniel Král' and Sergey Norin)

## Abstract

An important instance of the Caccetta-Häggkvist conjecture asserts that an  $n$ -vertex digraph with minimum outdegree at least  $n/3$  contains a directed triangle. Improving on a previous bound of  $0.3532n$  due to Hamburger, Haxell, and Kostochka we prove that a digraph with minimum outdegree at least  $0.3465n$  contains a directed triangle. The proof is an application of a recent combinatorial calculus developed by Razborov. This calculus enables one to formalize common techniques in the area (such as induction or the Cauchy-Schwartz inequality). In the talk I shall describe Razborov's method in general, and its application to the setting of the Caccetta-Häggkvist Conjecture.
